

Chapter 3: Processes

Chapter 3: Processes

Process Concept

Process Scheduling

Operations on Processes

Interprocess Communication

Examples of IPC Systems

Communication in Client-Server Systems

Objectives

To introduce the notion of **a process** -- a **program in execution**, which **forms** the **basis** of **all computation**

To describe the various features of processes, including **scheduling, creation and termination, and communication**

To explore **interprocess communication** using **shared memory** and **message passing**

To describe communication in **client-server** systems

Process Concept

An operating system executes a variety of programs:

Batch system – jobs

Time-shared systems – **user programs or tasks**

Textbook uses the **terms job and process** almost interchangeably

Process – a program in execution; process execution must **progress in sequential fashion**

Multiple parts

The **program code**, also called **text section**

Current **activity** including **program counter**, processor **registers**

Stack containing **temporary data**

- ▶ Function **parameters**, **return addresses**, **local variables**

Data section containing **global variables**

Heap containing **memory dynamically allocated** during run time

Process Concept (Cont.)

Program is **passive** entity stored on disk (**executable file**),
process is **active**

Program becomes process when **executable** file loaded into
memory

Execution of program started via **GUI mouse** clicks, command
line entry of its name, etc

One **program** can be several processes

Consider **multiple users** executing the same program

Process in Memory

Process State

As a process executes, it changes **state**

new: The process is **being created**

running: Instructions **are being executed**

waiting: The process is waiting **for some event to occur**

ready: The process is **waiting to be assigned to a processor**

terminated: The process has **finished execution**

Diagram of Process State

Process Control Block (PCB)

Information associated with each process
(also called **task control block**)

Process state – **running, waiting**, etc

Program counter – location of instruction to next execute

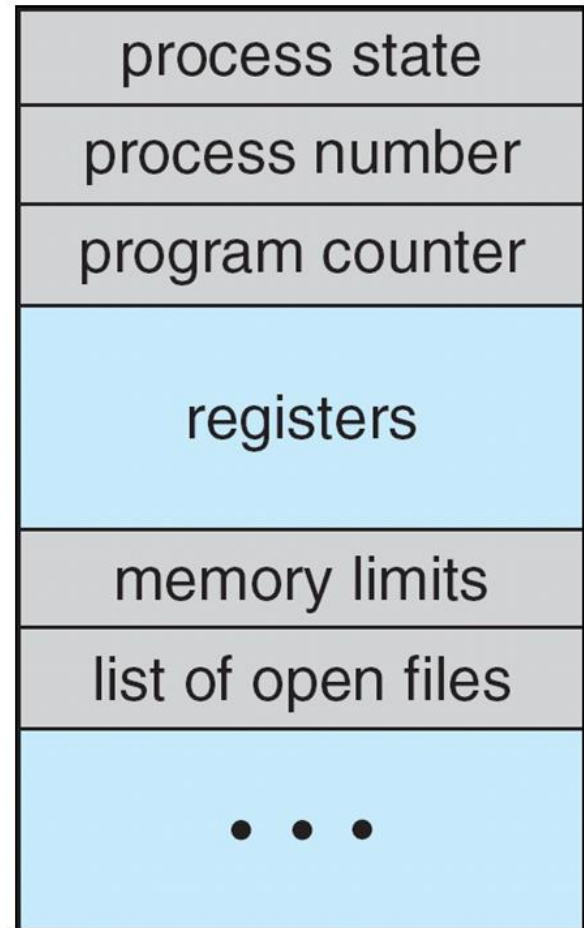

CPU registers – contents of all process-centric registers

CPU scheduling information- priorities, scheduling **queue pointers**

Memory-management information – memory **allocated to** the process

Accounting information – CPU used, clock time **elapsed since start**, time limits

I/O status information – I/O devices **allocated to process**, list of open files

CPU Switch From **Process0** to **Process1**

Threads

So far, process has a single thread of execution

Consider having multiple program counters per process

Multiple locations can execute at once

▶ **Multiple threads of control** -> **threads**

Must then have storage for thread details, multiple program counters in PCB

See next chapter

Process Representation in Linux

Represented by the C structure `task_struct`

```
pid t_pid; /* process identifier */
long state; /* state of the process */
unsigned int time_slice /* scheduling information */
struct task_struct *parent; /* this process's parent */
struct list_head children; /* this process's children */
struct files_struct *files; /* list of open files */
struct mm_struct *mm; /* address space of this process */
```

Process Scheduling

Maximize CPU use, quickly switch processes onto CPU for time sharing

Process scheduler selects among available processes for next execution on CPU

Maintains scheduling queues of processes

Job queue – set of all processes in the system

Ready queue – set of all processes residing in main memory, ready and waiting to execute

Device queues – set of processes waiting for an I/O device

Processes migrate among the various queues

Ready Queue And Various I/O Device Queues

Representation of Process Scheduling

Queueing diagram represents queues, resources, flows

Schedulers

Short-term scheduler (or **CPU scheduler**) – selects which **process** should be **executed next and allocates CPU**

Sometimes the only **scheduler** in a system

Short-term scheduler is invoked **frequently** (**milliseconds**) \Rightarrow (must be fast)

Long-term scheduler (or **job scheduler**) – selects which processes should be **brought into the ready queue**

Long-term scheduler is invoked **infrequently** (**seconds, minutes**) \Rightarrow (may be slow)

The long-term scheduler controls the **degree of multiprogramming**

Processes can be described as either:

I/O-bound process – spends more time doing I/O than computations, many **short CPU bursts**

CPU-bound process – spends more time doing computations; few very **long CPU bursts**

Long-term scheduler strives for good **process mix**

Addition of Medium Term Scheduling

Medium-term scheduler can be added if degree of multiple programming needs to decrease

Remove **process** from memory, store on disk, bring back in from disk to continue execution: **swapping(Virtual Memory)**

Multitasking in Mobile Systems

Some **mobile systems** (e.g., early version of **iOS**) allow only one process to run, others **suspended(暫停)**

Due to screen real estate, user interface limits **iOS provides** for a

Single foreground process- **controlled via user interface**

Multiple background processes— in memory, running, but not on the **display**, and with limits

Limits include single, short task, receiving notification of **events**, specific **long-running tasks like audio playback**

Android **runs foreground and background**, with fewer limits

Background process uses a **service** to **perform tasks**

Service can keep running even if background process is suspended

Service has no user interface, small memory use

Context Switch

When **CPU switches to another process**, the system must **save the state** of the old process and load the **saved state** for the new process via a **context switch**

Context of a process represented in the **PCB**

Context-switch **time** is **overhead**; the **system** does no useful work while **switching**

The **more complex** the OS and the PCB → **the longer** the context switch

Time dependent on hardware support

Some hardware provides multiple sets of registers per CPU
→ **multiple contexts loaded at once**

Operations on Processes

System must provide mechanisms for:

process **creation**,

process **termination**,

and so on as detailed next

Process Creation

Parent process create **children** processes, which, in turn create other processes, **forming a tree** of processes

Generally, process identified and managed via a **process identifier (pid)**

Resource sharing options

- Parent and children **share all resources**

- Children share subset of **parent's resources**

- Parent and child **share no resources**

Execution options

- Parent and children **execute concurrently**

- Parent waits until **children terminate**

A Tree of Processes in Linux

Process Creation (Cont.)

Address **space**

Child duplicate of parent

Child has a program loaded into it

UNIX examples

fork() system call creates new process

exec() system call used after a **fork()** to replace the process' memory space with a new program(下面是例子)

C Program Forking Separate Process

```
#include <sys/types.h>
#include <stdio.h>
#include <unistd.h>

int main()
{
    pid_t pid;

    /* fork a child process */
    pid = fork();

    if (pid < 0) { /* error occurred */
        fprintf(stderr, "Fork Failed");
        return 1;
    }
    else if (pid == 0) { /* child process */
        execlp("/bin/ls", "ls", NULL);
    }
    else { /* parent process */
        /* parent will wait for the child to complete */
        wait(NULL);
        printf("Child Complete");
    }

    return 0;
}
```

Creating a Separate Process via **Windows API**

```
#include <stdio.h>
#include <windows.h>

int main(VOID)
{
    STARTUPINFO si;
    PROCESS_INFORMATION pi;

    /* allocate memory */
    ZeroMemory(&si, sizeof(si));
    si.cb = sizeof(si);
    ZeroMemory(&pi, sizeof(pi));

    /* create child process */
    if (!CreateProcess(NULL, /* use command line */
        "C:\\WINDOWS\\system32\\mspaint.exe", /* command */
        NULL, /* don't inherit process handle */
        NULL, /* don't inherit thread handle */
        FALSE, /* disable handle inheritance */
        0, /* no creation flags */
        NULL, /* use parent's environment block */
        NULL, /* use parent's existing directory */
        &si,
        &pi))
    {
        fprintf(stderr, "Create Process Failed");
        return -1;
    }
    /* parent will wait for the child to complete */
    WaitForSingleObject(pi.hProcess, INFINITE);
    printf("Child Complete");

    /* close handles */
    CloseHandle(pi.hProcess);
    CloseHandle(pi.hThread);
}
```

Process Termination

Process **executes last statement** and then asks the operating system to **delete** it using the **exit()** system call.

Returns status data from **child to parent** (via **wait()**)

Process' resources are deallocated **by operating system**

Parent may **terminate the execution** of children processes using the **abort()** system call. Some reasons for doing so:

Child has exceeded allocated resources

Task assigned to child is no longer required

The **parent is exiting** and the operating systems does **not** allow a **child to continue** if its **parent terminates**

Process Termination

Some operating systems do not allow child to exist if its parent has terminated. If a process terminates, then all its children must also be terminated.

cascading termination. All children, grandchildren, etc. are terminated.

The termination is initiated by the operating system.

The parent process may wait for termination of a child process by using the **wait()** system call. The call returns status information and the pid of the terminated process

```
pid = wait(&status);
```

If no parent waiting (did not invoke **wait()**) process is a **zombie**(殭屍)跟前面Termination設計type有關 要避免

If parent terminated without invoking **wait**, process is an **orphan**(孤兒)跟前面Termination設計type有關 要避免

Multiprocess Architecture – Chrome Browser

Many web browsers ran as single process (some still do)

If one web site causes trouble, entire browser can hang or crash

Google Chrome Browser is **multiprocess** with 3 different types of processes:

Browser process manages user **interface**, disk and network I/O

Renderer process renders web pages, deals with HTML, Javascript. A new renderer **created for each website opened**

- ▶ Runs in **sandbox** restricting disk and network I/O, minimizing effect of security exploits

Plug-in process for each type of plug-in

Interprocess Communication

Processes within a system may be **independent** or **cooperating**

Cooperating process can **affect** or be affected **by other processes**, including **sharing data**

Reasons for **cooperating** processes:

- Information** sharing

- Computation** speedup

- Modularity**

- Convenience**

Cooperating processes need **interprocess communication** (**IPC**)

Two models of IPC

- Shared memory**

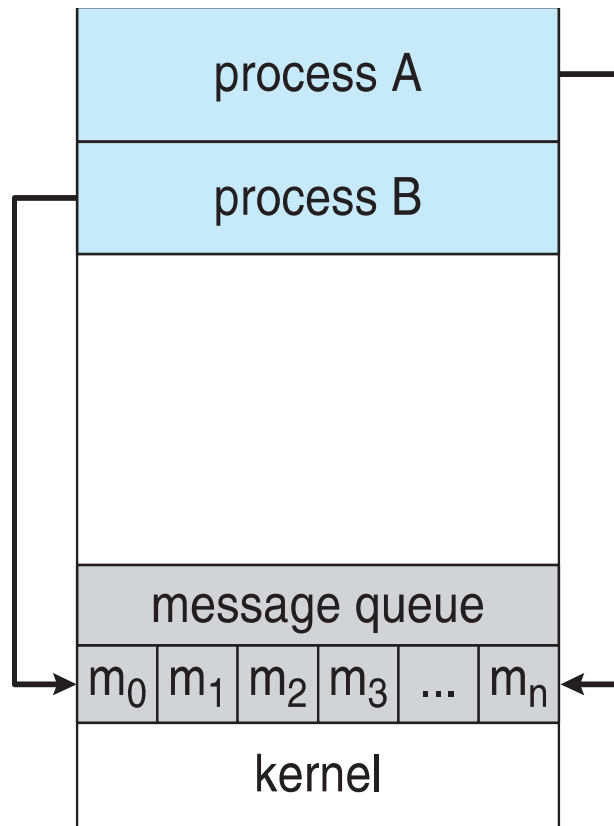

- Message passing**

Communications Models

(a) Message passing. (b) shared memory.

(a)

(b)

Cooperating Processes

Independent process cannot affect or be affected by the execution of another process

Cooperating process can affect or be affected by the execution of another process

Advantages of process cooperation

- Information sharing

- Computation speed-up

- Modularity

- Convenience

Producer-Consumer Problem

Paradigm for cooperating processes, *producer* process produces information that is consumed by a *consumer* process

unbounded-buffer places no practical limit on the size of the buffer

bounded-buffer assumes that there is a fixed buffer size

Bounded-Buffer – Shared-Memory Solution

Shared data

```
#define BUFFER_SIZE 10
typedef struct {
    . . .
} item;

item buffer[BUFFER_SIZE];
int in = 0;
int out = 0;
```

Solution is correct, but can only use BUFFER_SIZE-1 elements

Bounded-Buffer – Producer

```
item next_produced;
while (true) {
    /* produce an item in next produced */
    while (((in + 1) % BUFFER_SIZE) == out)
        ; /* do nothing */
    buffer[in] = next_produced;
    in = (in + 1) % BUFFER_SIZE;
}
```

Bounded Buffer – Consumer

```
item next_consumed;
while (true) {
    while (in == out)
        ; /* do nothing */
    next_consumed = buffer[out];
    out = (out + 1) % BUFFER_SIZE;

    /* consume the item in next consumed */
}
```

Interprocess Communication – Shared Memory

An **area of memory** shared among **the processes** that wish to **communicate**

The communication is under the control of the users processes not the operating system.

Major issues is to **provide mechanism** that will allow the **user processes** to synchronize their actions when they **access shared memory**.

Synchronization is discussed in great details in Chapter 5.

Interprocess Communication – Message Passing

Mechanism for processes to communicate and to **synchronize** their actions

Message system – processes communicate with each other without **resorting** to **shared variables**

IPC facility provides two operations:

send(message)

receive(message)

The **message size** is either **fixed** or **variable**

Message Passing (Cont.)

If processes P and Q wish to communicate, they need to:

Establish a **communication link** between them

Exchange messages via **send/receive**

Implementation issues:

How are **links** established?

Can a link be **associated with** more than two processes?

How many **links can there be between every pair** of communicating processes?

What is the **capacity** of a link?

Is the size of a message that the link can accommodate **fixed or variable**?

Is a link **unidirectional** or **bi-directional**?

Message Passing (Cont.)

Implementation of communication link

Physical:

- ▶ Shared memory
- ▶ Hardware bus
- ▶ Network

Logical:

- ▶ Direct or indirect
- ▶ Synchronous or asynchronous
- ▶ Automatic or explicit明確buffering

Direct Communication

Processes must name each other explicitly:

send (*P*, *message*) – send a message to process P

receive(*Q*, *message*) – receive a message from process Q

Properties of communication link

Links are established automatically

A link is associated with exactly one pair of communicating processes

Between each pair there exists exactly one link

The link may be unidirectional, but is usually bi-directional

Indirect Communication

Messages are directed and received from **mailboxes** (also referred to as ports)

Each **mailbox** has a **unique id**

Processes can **communicate only** if they share a mailbox

Properties of communication link

Link established only if **processes share a common mailbox**

A link may be **associated with many processes**

Each pair of processes **may share several communication links**

Link may **be unidirectional or bi-directional**

Indirect Communication

Operations

create a new mailbox (port)

send and receive messages through mailbox

destroy a mailbox

Primitives are defined as:

send(*A, message*) – send a message to **mailbox A**

receive(*A, message*) – receive a **message** from mailbox A

Indirect Communication

Mailbox sharing

P_1 , P_2 , and P_3 share mailbox A

P_1 sends; P_2 and P_3 receive

Who gets the message?

Solutions

Allow a link to be associated with at most two processes

Allow only one process at a time to execute a receive operation

Allow the system to select arbitrarily the receiver.
Sender is notified who the receiver was.

Synchronization

Message passing may be either blocking or non-blocking

Blocking is considered **synchronous**

Blocking send -- the sender is blocked until the message is received

Blocking receive -- the receiver is blocked until a message is available

Non-blocking is considered **asynchronous**

Non-blocking send -- the sender sends the message and continue

Non-blocking receive -- the receiver receives:

A valid message, or

Null message

Different combinations possible

If both send and receive are blocking, we have a **rendezvous**

Synchronization (Cont.)

Producer-consumer becomes trivial

```
message next_produced;  
while (true) {  
    /* produce an item in next produced */  
    send(next_produced);  
}
```

```
message next_consumed;  
while (true) {  
    receive(next_consumed);  
  
    /* consume the item in next consumed */  
}
```

Buffering

Queue of messages attached to the link.

implemented in one of three ways

1. **Zero capacity** – no messages are queued on a link.
Sender must wait for receiver (rendezvous)
2. **Bounded capacity** – finite length of n messages
Sender must wait if link full
3. **Unbounded capacity** – infinite length
Sender never waits

Examples of IPC Systems - POSIX

POSIX Shared Memory

Process first creates shared memory segment

```
shm_fd = shm_open(name, O_CREAT | O_RDWR, 0666);
```

Also used to open an existing segment to share it

Set the size of the object

```
ftruncate(shm_fd, 4096);
```

Now the process could write to the shared memory

```
sprintf(shared_memory, "Writing to shared  
memory");
```

IPC POSIX Producer

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <fcntl.h>
#include <sys/shm.h>
#include <sys/stat.h>

int main()
{
    /* the size (in bytes) of shared memory object */
    const int SIZE = 4096;
    /* name of the shared memory object */
    const char *name = "OS";
    /* strings written to shared memory */
    const char *message_0 = "Hello";
    const char *message_1 = "World!";

    /* shared memory file descriptor */
    int shm_fd;
    /* pointer to shared memory object */
    void *ptr;

    /* create the shared memory object */
    shm_fd = shm_open(name, O_CREAT | O_RDWR, 0666);

    /* configure the size of the shared memory object */
    ftruncate(shm_fd, SIZE);

    /* memory map the shared memory object */
    ptr = mmap(0, SIZE, PROT_WRITE, MAP_SHARED, shm_fd, 0);

    /* write to the shared memory object */
    sprintf(ptr,"%s",message_0);
    ptr += strlen(message_0);
    sprintf(ptr,"%s",message_1);
    ptr += strlen(message_1);

    return 0;
}
```

IPC POSIX Consumer

```
#include <stdio.h>
#include <stdlib.h>
#include <fcntl.h>
#include <sys/shm.h>
#include <sys/stat.h>

int main()
{
    /* the size (in bytes) of shared memory object */
    const int SIZE = 4096;
    /* name of the shared memory object */
    const char *name = "OS";
    /* shared memory file descriptor */
    int shm_fd;
    /* pointer to shared memory object */
    void *ptr;

    /* open the shared memory object */
    shm_fd = shm_open(name, O_RDONLY, 0666);

    /* memory map the shared memory object */
    ptr = mmap(0, SIZE, PROT_READ, MAP_SHARED, shm_fd, 0);

    /* read from the shared memory object */
    printf("%s", (char *)ptr);

    /* remove the shared memory object */
    shm_unlink(name);

    return 0;
}
```

Examples of IPC Systems - Mach

Mach communication is message based

Even system calls are messages

Each **task** gets **two mailboxes** at creation- Kernel and Notify

Only three system calls needed for message transfer

`msg_send()`, `msg_receive()`, `msg_rpc()`

Mailboxes needed for **commuication**, **created** via

`port_allocate()`

Send and receive are flexible, for example four options if mailbox full:

- ▶ Wait **indefinitely**
- ▶ Wait **at most n milliseconds**
- ▶ Return **immediately**
- ▶ Temporarily **cache a message**

Examples of IPC Systems – Windows

Message-passing centric via **advanced local procedure call (LPC)** facility

Only works between processes on the same system

Uses ports (like mailboxes) to establish and maintain communication channels

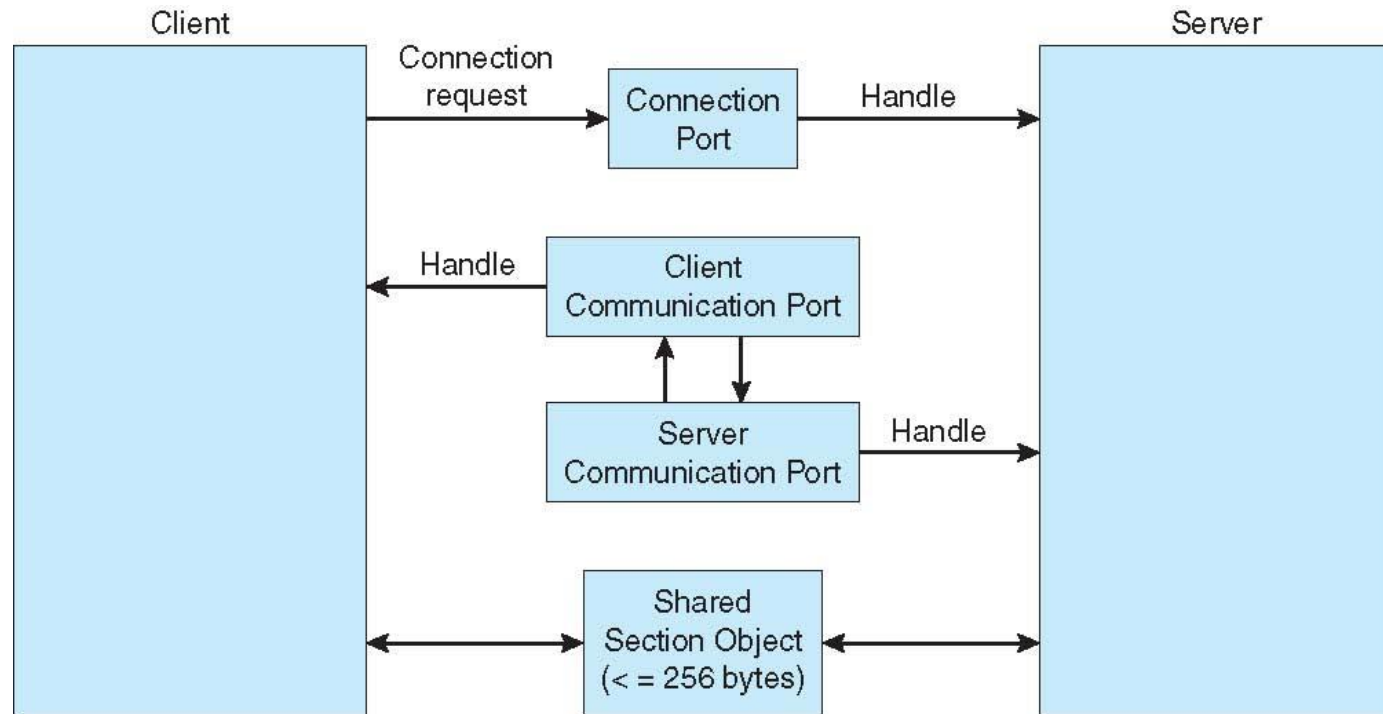

Communication works as follows:

- ▶ The client opens a handle to the subsystem's **connection port** object.
- ▶ The **client** sends a connection **request**.
- ▶ The server creates **two private communication ports** and returns the handle to one of them to the client.
- ▶ The client and server use the corresponding port handle to send messages or callbacks and to listen for replies.

Local Procedure Calls in Windows

Communications in Client-Server Systems

Sockets

Remote Procedure Calls

Pipes

Remote Method Invocation (Java)

Sockets

A **socket** is defined as an endpoint for communication

Concatenation of IP address and **port** – a number included at start of message packet to differentiate network services on a host

The socket **161.25.19.8:1625** refers to port **1625** on host **161.25.19.8**

Communication consists between a pair of sockets

All ports below 1024 are **well known**, used for standard services

Special IP address 127.0.0.1 (**loopback**) to refer to system on which process is running

Socket Communication

Sockets in Java

Three types of sockets

**Connection-oriented
(TCP)**

Connectionless (UDP)

MulticastSocket
class— data can be sent
to multiple recipients

Consider this “Date” server:

```
import java.net.*;
import java.io.*;

public class DateServer
{
    public static void main(String[] args) {
        try {
            ServerSocket sock = new ServerSocket(6013);

            /* now listen for connections */
            while (true) {
                Socket client = sock.accept();

                PrintWriter pout = new
                    PrintWriter(client.getOutputStream(), true);

                /* write the Date to the socket */
                pout.println(new java.util.Date().toString());

                /* close the socket and resume */
                /* listening for connections */
                client.close();
            }
        }
        catch (IOException ioe) {
            System.err.println(ioe);
        }
    }
}
```

Remote Procedure Calls

Remote procedure call (RPC) abstracts procedure calls between processes on networked systems

Again uses ports for service differentiation

Stubs – client-side proxy for the actual procedure on the server

The client-side stub locates the server and **marshalls** the parameters

The server-side stub receives this message, unpacks the marshalled parameters, and performs the procedure on the server

On Windows, stub code compile from specification written in **Microsoft Interface Definition Language (MIDL)**

Remote Procedure Calls (Cont.)

Data representation handled via **External Data Representation (XDL)** format to account for different architectures

Big-endian and **little-endian**

Remote communication has more failure scenarios than local

Messages can be delivered ***exactly once*** rather than ***at most once***

OS typically provides a rendezvous (or **matchmaker**) service to connect client and server

Execution of RPC

Pipes

Acts as a conduit allowing two processes to communicate

Issues:

Is communication unidirectional or bidirectional?

In the case of two-way communication, is it half or full-duplex?

Must there exist a relationship (i.e., **parent-child**) between the communicating processes?

Can the pipes be used over a network?

Ordinary pipes – cannot be accessed from outside the process that created it. Typically, a parent process creates a pipe and uses it to communicate with a child process that it created.

Named pipes – can be accessed without a parent-child relationship.

Ordinary Pipes

Ordinary Pipes allow communication in standard producer-consumer style

Producer writes to one end (the **write-end** of the pipe)

Consumer reads from the other end (the **read-end** of the pipe)

Ordinary pipes are therefore unidirectional

Require parent-child relationship between communicating processes

Windows calls these **anonymous pipes**

See Unix and Windows code samples in textbook

Named Pipes

Named Pipes are more powerful than ordinary pipes

Communication is bidirectional

No parent-child relationship is necessary between the communicating processes

Several processes can use the named pipe for communication

Provided on both UNIX and Windows systems

End of Chapter 3
